

## Lab 3

### Goals for this Lab

1. Write a binary tree class.

### Task Description

Your goal for this lab is to write a binary tree.

### The BinaryTree Class

The public constructors and methods required for the `BinaryTree` class are listed here. For this lab the tree will only need to handle integers.

<b>BinaryTree()</b>	Construct an empty <code>BinaryTree</code> object.
<b>int size()</b>	Return the size (number of items) in this <code>BinaryTree</code> .
<b>boolean isEmpty()</b>	Return <code>true</code> if this <code>BinaryTree</code> has no items. (This is the same as the size equal to zero.) Return <code>false</code> if the size is greater than zero.
<b>void add(int value)</b>	Add the given element, <code>value</code> , to the tree.
<b>bool exists(int value)</b>	Return <code>true</code> if the element exists in the tree, otherwise return <code>false</code> .
<b>Integer max()</b>	Return the largest element in the tree.
<b>Integer min()</b>	Return the smallest element in the tree.

### Requirements

1. Your class must be named `BinaryTree`.
2. Your class must provide the methods listed above for construction, accessing, and manipulating `BinaryTree` objects.
3. Other than for testing purposes, your `BinaryTree` class should do no input or output.

### Testing

This lab will be manually tested. Make sure to test all cases.

### Notes

It may be useful to be able to print out the tree during development/debugging. This will be easiest by creating a `toString()` method for your `BinaryTree` class, but it is not required.
